The Multiple Stress Creep Recovery (MSCR) Test – AASHTO T 350

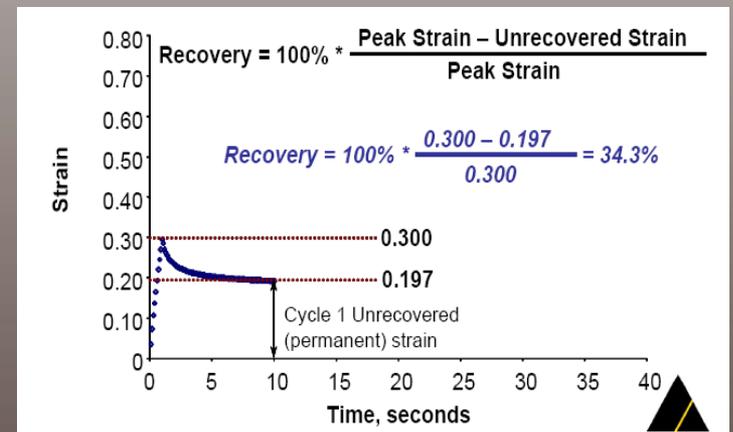

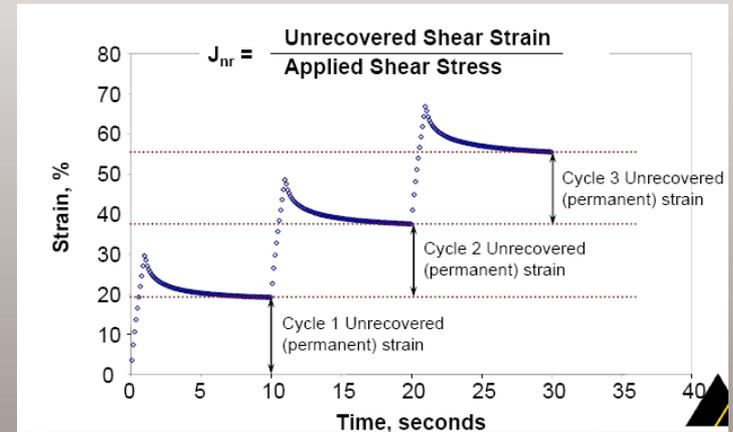

- During the creep interval, a material is subjected to a load (stress) for a fixed amount of time while the resulting deformation (strain) is measured. Applied load interval.
- The recovery interval immediately follows the creep interval wherein the load (stress) is completely removed and the recoil (recovery) of the material is measured. No load interval.
- The controlled and measured parameters are applied stress and resulting strain.
- The creep interval time is 1 second. The recovery interval time is 9 seconds. For a total cycle time of 10 seconds.
- 20 cycles at 0.1 kPa and 10 cycles at 3.2 kPa are conducted.

Example Showing 3 Cycles at the Two Stress Levels

MSCR Test – Parameters

- J_{nr} , or **non-recoverable compliance**, is simply the unrecovered strain relative to the applied stress.
- Numerically, it is the unrecovered strain over the applied stress.
- **Percent recovery** is how thoroughly the sample returns to its previous shape after being stretched (creep) and then relaxed (recovered).
- Numerically, it is the difference between the strain at the end of the recovery period and the peak strain at the end of the creep period relative to the peak strain.

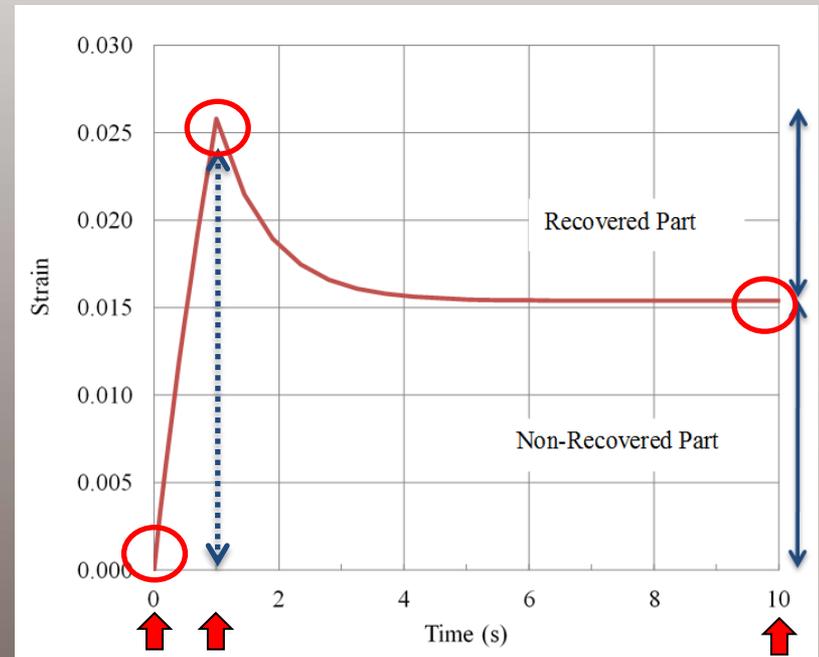

MSCR Test – Analysis

■ Values needed for calculations:

- ε_0 : Initial strain (@ 0 second)
- ε_C : Strain after the creep portion (@ 1 second)
- ε_r : Strain at the end of cycle (@ 10 seconds)

- The rest is **mathematical calculations** based on AASHTO T 350.

Analysis Method

- DSR Software output: (version)
 - Final calculated results
 - Raw data
- Manual calculations:
 - Own developed spreadsheet
 - Template provided by vendor

Manual Calculations

- If strain values **are available** at those exact times:
 - Straight forward calculations
 - Double check with other methods?
- If strain values **are not** available at those exact times:
 - Extrapolation ?
 - Interpolation ?

Example of Raw Data

Available strain values at those exact desired times

■ Data Sampling:

- Creep Region:
10 data points = 1.00 sec
- Recovery Region:
90 data points = 9.00 sec
- Sampling Interval:
0.1 sec

Time [s]	Strain [%]	Creep Compliance [1/Pa]	Shear Stress [Pa]	Torque [mNm]	Temperature [°C]
0.10	1.0681	0.000107	100	0.307	58

DSR#2

- Creep Region = 27 Data Pts = 0.953 sec
- Recovery Region = 63 Data Pts = 9.706 sec
- Sampling Interval = 0.013 - 0.402 sec

Test Time

$$\begin{aligned} &= (27 + 63) * 10 \\ &= 900 \text{ Data Pts} \\ &= 99.71 \text{ sec} \end{aligned}$$

Verifying the Analysis Method

Available strain values not at the exact desired times

- How are data explicit times determined ?
- Interpolation or Extrapolation ?
 - Effect on the results & outcome ?
 - How many points before or after should be used ?
- User or Vendor responsibility ?
 - Who needs to keep them updated ?
 - Have DSR vendors already taken action ?

Standardized Method ?

- Can this be another source of variability?
- Need to standardize the method of analysis?
